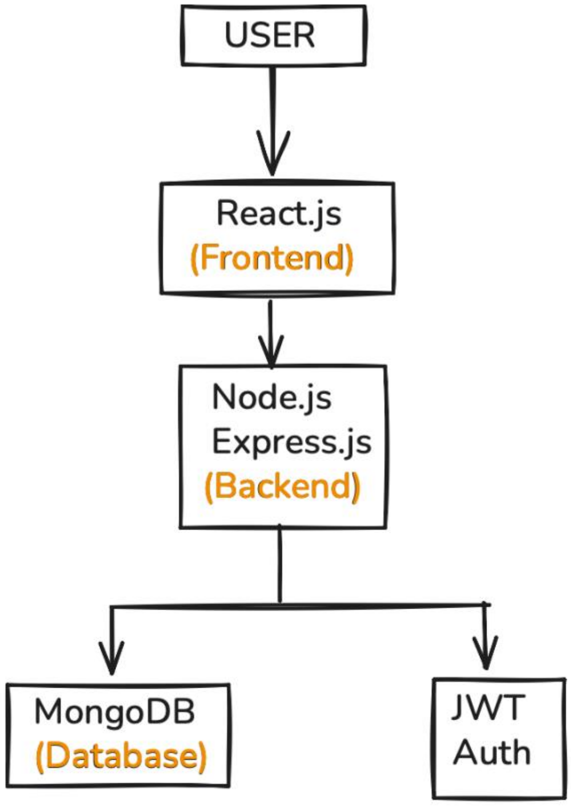
<u>Technical Architecture</u>:



<u>Description</u>:

The **House Rent Application** is developed using the **MERN Stack (MongoDB, Express.js, React.js, and Node.js)** and follows a **client-server architecture**. The system is divided into two main parts: the frontend and the backend. The frontend is built using **React.js**, which provides an interactive and responsive user interface for tenants, property owners, and administrators. Users can browse available properties, search based on their preferences, view property details, book visits, and manage their profiles through the frontend.

The backend is developed using **Node.js** and **Express.js**, which handle all server-side operations and business logic. The backend processes user requests, manages property listings, handles booking operations, authenticates users, and communicates with the database. All communication between the frontend and backend takes place through **RESTful APIs**, ensuring efficient and secure data exchange.

For data storage, the application uses **MongoDB**, a NoSQL database that stores user information, property details, bookings, reviews, and other application data. MongoDB provides flexibility, scalability, and fast retrieval of information. User authentication and authorization are secured using **JWT (JSON Web Tokens)**, allowing only authorized users to access protected features.

Overall, the architecture ensures smooth interaction between users and the system while providing a scalable, secure, and efficient platform for managing rental properties and connecting tenants directly with property owners.
